Riley Blacklock

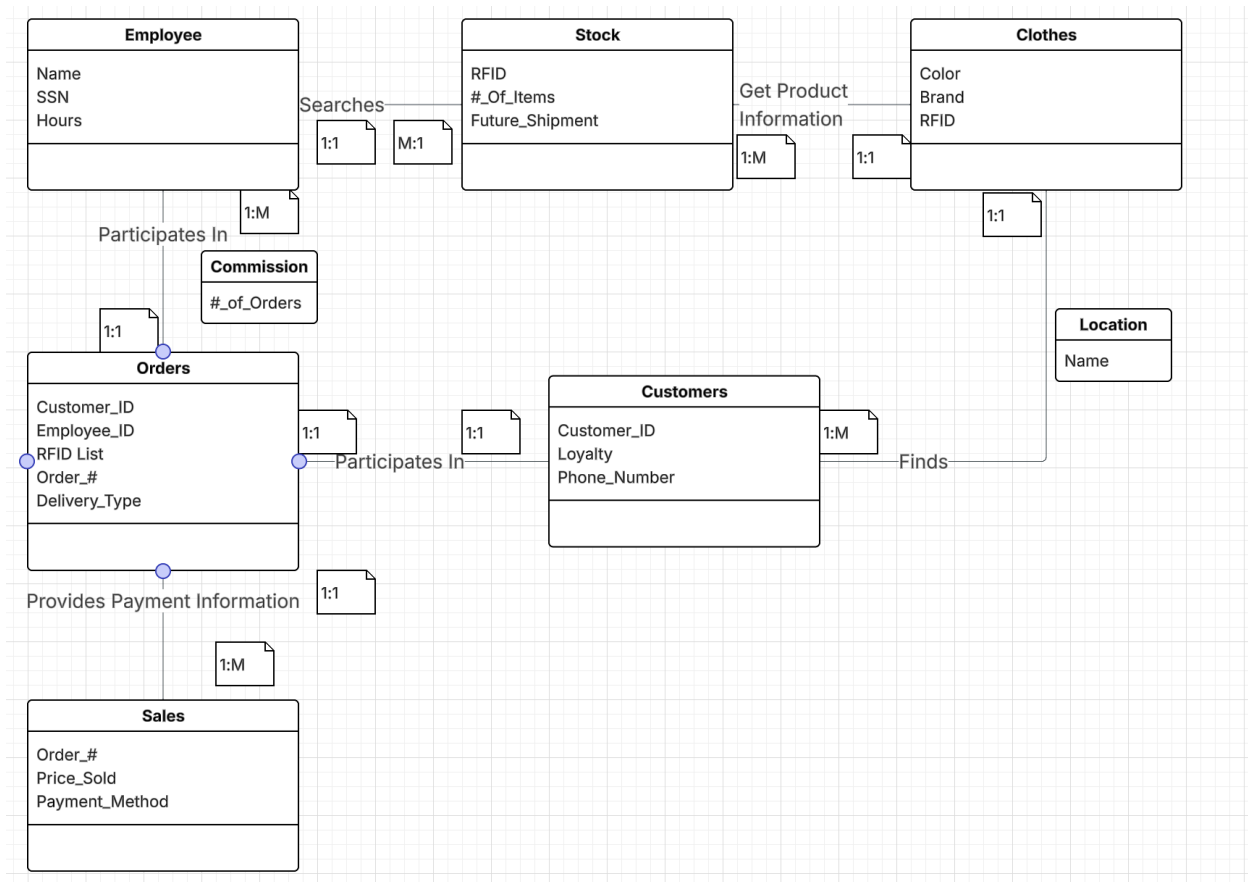

Description

The system we are choosing is a clothing store management system which is designed to support the daily operations of a retail clothing store. The system will help organize and manage store activities such as inventory control, sales transactions, customer purchases, an employee catalog and their access tokens, and product restocking. We will use a centralized database system to store accurate and up-to-date information about clothing items, stock levels, RFID, customer orders, and employee activity. Having such a system is essential for the success of running a clothing store. The primary users of the system are store employees, managers, and the business owners. Employees will use this system to process transactions, returns, buy online pick up in store orders, and ship out of store orders. Managers and owners will use it to monitor inventory levels, review sales, and make business decisions based on store data. The system will track important data such as sales performance, register activity, performance of the store in general, and an employee catalog. It will also support the workflow of receiving inventory, displaying products for sale, completing customer purchases, and updating the stock of the item after every transaction.

Scope

- The system will store information about clothing items, including name, brand, size, color, category, and price.
- The system will track inventory levels for each clothing item currently available in the store.
- The system will record customer purchases and generate sales transaction records.
- The system will allow employees to search for products by category, size, color, or brand.
- The system will track when items need to be restocked based on low inventory levels.
- The system will store employee information and connect employees to the sales they ring up.
- The system will maintain records of suppliers for ordering and restocking merchandise.
- The system will provide managers with reports on sales performance

UML Overview

Constraints

- Unique SSN per Employee
- Unique Customer ID per customer
- Unique Order Number per order
- Hours must be numeric
- Stock must contain all items in the store
- Clothes database must allow queries for search
- Customer ID must be generated on first order
- Sales must calculate the final purchase price of the order
- Orders must contain a list of RFIDs to present all items in the order
